RETOUCHING TOOLS FROM THE POST-PALAEOLITHIC PERIOD IN SOUTHEAST EUROPE

Abstract

One of the earliest confirmed uses of osseous raw materials was for retouching, sharpening and repairing stone tools, dating from the Lower Palaeolithic and throughout the Pleistocene period. Considerable changes to subsistence strategies, technology, and overall lifeways occurred among European hunter-gatherer communities during the Holocene. In turn, the role of retouching tools was also modified. Although less common, retouching tools were still present among the Mesolithic and Neolithic communities across Europe. This paper provides an overview of the available evidence for the presence of retouching tools in the Mesolithic and Neolithic, focussing on southeast Europe. Their technological traits, distribution, functions and their significance within Mesolithic and Neolithic societies will be discussed.

Keywords

Mesolithic; Neolithic; Southeast Europe; Bone technology; Retouching tools

Introduction

Retouchers are artefacts used for retouching, repairing and/or sharpening stone tools. They may be made out of different materials, including bone, antler or teeth, and may be used in their natural form or modified (Patou-Mathis and Schwab, 2002). Retouchers can be easily distinguished from other tools by the specific use traces, usually consisting of one or several zones of use with small punctiform pits and/or parallel linear marks on the distal ends of their surfaces. Use traces are often dense and overlapping, creating small, localized surfaces of damage on the bones (Leonardi, 1979; Averbouh, 2000; Patou-Mathis and Schwab, 2002; Schwab, 2002; Karavanić and Šokec, 2003; Mallye et al., 2012; David and Sørensen, 2016). Although these characteristic marks are clearly the result of stone working, different types of stone working tools (e.g., punches, pressure flakers, hammers, retouching tools) cannot always be easily distinguished.

Retouching tools are one of the earliest types of artefacts made from osseous materials, and some of the earliest recognized bone tools (e.g., Henri-Martin, 1906, 1908; Siret, 1925). A great deal of attention has been paid to the occurrence of osseous retouching tools during different stages of the Palaeolithic and their importance for studying early
stages of technology (e.g., Chase, 1990). However, their study is often neglected during later periods, particularly from the Holocene. One of the reasons may be the fact that, for a very long time, most of the studies of osseous industries from later prehistoric periods focused mainly on morphology and on typological classification based on forms. Furthermore, retouching tools may have been overlooked in those sites where faunal remains were not carefully collected, not thoroughly analysed, or where studies of osseous industries were restricted to formal tools. Therefore, it is reasonable to expect that the quantity and diversity of such finds, as well as their geographical and chronological distribution, will increase with future analyses.

The Holocene period brought on important changes among European hunter-gatherer communities, in subsistence practices, lifeways, and also technology (see Bailey and Spikins, 2008, and references therein). As flint industries changed, so too did other associated technologies, including retouching tools. As a general trend, they became less common over the course of the Holocene. Although they were *ad hoc* tools to a certain extent, they often display more careful manufacture, more formal shapes and evidence of longer use lives. Overall, they were still a relatively rare group of “tool-making tools” (Chase, 1990), i.e., tools used exclusively for the production and maintenance of other tools.

In this paper, I offer a short overview of the retouching tools of the Mesolithic and the Neolithic periods, with special focus on the region of southeast Europe (Figure 1). Their role in daily activities and craft production will be discussed.

Retouching tools in the Mesolithic

Mesolithic in the Iron Gates

The Iron Gates region is a part of the Danube valley, today forming the border between Serbia and Romania, where several sites dated to the Mesolithic were discovered: Lepenski Vir, Vlasac, Padina, Hajdučka Vodenica, Schela Cladovei, Ostrovul Corbului, Ostrovul Banului, Icoana and others (Bonsall, 2008; see also Radovanović, 1996, and references therein). These Mesolithic communities practiced fishing and large game hunting, and their material culture included lithic and osseous tools, weapons and non-utilitarian items, such as ornamented stones and sculptures (Srejović and Letica, 1978; see also Radovanović, 1996, and references therein). Unfortunately, most of the finds were collected during rescue excavation projects from the 1960s-1980s, when faunal material was hand-collected, sometimes in haste, and not all of it was thoroughly examined. Furthermore, the taphonomic conditions for bone survival were unfavourable at some of the sites, so the quantity and the preservation of bone artefacts are sometimes very poor (e.g., at Kula; Vitezović, 2011b; see also Radovanović, 1996, and references therein).

The chipped stone industry included artefacts made from quartz, quartzite, silicate rocks, obsidian, flint and chalcedony (Radovanović, 1981), with quartz and quartzite particularly abundant at some of the sites (e.g., at Kula; Sladić, 1986, 2007; see also Radovanović, 1996, and references therein). Retouched tools included end and side scrapers, retouched flakes, burins, retouched blades, perforators, awls, retouched bladelets and geometric microliths, among others (Radovanović, 1981, 1996). The abundance of retouched tools varied from site to site and over time. For example, at Râzvâra they comprised only 1.6% of the total chipped stone assemblage, at Vlasac between 5.0% and 6.6% in different horizons, 15.0-23.0% at Padina and 16.0-31.9% at Ostrovul Banului (Radovanović, 1996:233). Osseous industries included a large number of antler tools, mainly implements with working edges used for cutting/chopping (chisels, wedges, axes or mattocks), and various hammers, scrapers, burnishers, pointed tools and weapons (projectile points and harpoons). Retouching tools are recognized from at least two sites. During the 1970s excavations at the site of Vlasac on the Serbian side of the Danube River, a large bone assemblage of almost 4000 artefacts was recovered and analysed mainly from a typological viewpoint (Srejović and Letica, 1978). Although the original report does not mention retouching tools, they can be recognized by specific use wear traces. These include one antler beam artefact with incised net decoration over its surface that was probably also used as a scraper or burnisher (Srejović and Letica, 1978:plate LXXVI) and perhaps a few other antler implements interpreted as cutting or percussion tools.

Two poorly reserved retouching tools were uncovered at Kula, another site on the Serbian side of the Danube (Vitezović, 2011b). One retoucher was made from a red deer (Cervus elaphus) antler tine segment. The base was simply cut or broken off and it has traces of scraping and whittling on its mesial side. The working tip is heavily worn and has deep, parallel incisions and grooves. The second tool is also made from red deer antler tine (Figure 2). The basal part has traces of grooving from the cut-and-break method used to detach the antler blank. The natural tip of the tine was preserved at the distal end and it was probably used as a punch. Deep, parallel grooves and incisions are visible over the entire distal and mesial portions. These traces are compatible with use as a retouching tool (Leonardi, 1979; Averbouh, 2000; Patou-Mathis and Schwab, 2002; Valensi, 2002; Karavanić and Šokec, 2003; Schwab, 2003; Mallye et al., 2012).

Vlasac and Kula have low numbers of retouched tools (Sladić, 1986, 2007; Radovanović, 1996), but this may be connected with preservation issues, recovery methods or differences in the character of the excavated portion of the site (such as activity areas). The circumstances of site occupation may be relevant, as it is not clear whether these settlements were occupied year-round and by all members of the community. The absence of retouchers at sites...
on the Romanian side of the Danube (Beldiman, 2007) may also be explained by these factors.

**Mesolithic in Europe**

Rich Mesolithic assemblages from northern and eastern Europe also yielded different osseous tools related to stone working. Retouching tools were reported from several sites of the Butovo culture, in the Volga-Oka region in Russia, such as Ozerki 5, Okaemovo 5, Ivanovskoe 7 and Stanovoe 4 (Zhilin, 2013, 2014). These tools were made from diverse raw materials: bear canines, beaver mandible fragments and incisors, different long bones, ribs and antlers. Bone retouchers, such as a rib segment of a large ungulate from Ivanovskoe 7, were not intentionally shaped, but simply selected from among broken pieces of bone. Unmodified bear canines

![Figure 2](image-url)

**Figure 2** a) Retouching tool from the site of Kula, Mesolithic; b) Detail.
were also used, generally displaying heavy damage from use as both intermediary tools and in direct retouching. These bear canines were relatively numerous at Ozerki 5, for example, where 13 such tools were discovered (Zhilin, 2013, 2014). Antler retouching tools are known from Stanovoe 4, made from a diversity of antler segments modified mainly by scraping, and one has traces of being repaired (Zhilin, 2014). Retouching tools made of beaver incisors from Ivanovskoe 7 and Stanovoe 4 were reworked several times and used for different purposes; their final function was for pressure flaking (Zhilin, 2014).

Rare finds of possible retouching tools were reported from other sites in the Baltic region (David and Pelegrin, 2009). Mesolithic sites in present-day Denmark and adjacent areas also yielded a number of osseous tools used in indirect and pressure lithic reduction. Most were made from red deer antler, but elk (Alces alces) antler and bone were also used. Four possible types of tools were identified: pectoral pressure sticks, punch tools, shoulder/elbow pressure sticks and lever pressure sticks (David and Sørensen, 2016).

Recent studies of the Mesolithic sites in the Adriatic region suggest that osseous retouching tools were used in these communities as well. For example, the site of Vlakno on the island of Dugi otok in Croatia yielded a relatively rich osseous industry, with a few antler tines possibly used for retouching flint (Radović et al., 2016).

Retouching tools in the Early Neolithic

Starčevo culture

The first farming communities in the central Balkans and south Pannonian plain are attributed to the Starčevo culture (roughly 6200-5500 BC; see Whittle et al., 2002), part of the Starčevo-Körös-Criş cultural complex. Numerous portable finds were uncovered from several dozen settlement sites that have been excavated up until the present day.

The chipped stone industry included the following retouched artefacts in varying abundances at different sites: retouched flakes, retouched blades (sometimes quite long), perforators, side scrapers,

Figure 3  a, b) Retouching tool from the site of Starčevo-Grad (Starčevo culture, Early Neolithic) with a groove at the base; c) Detail of usewear.
end scrapers and double side scrapers (see Šarić, 2014, and references therein). The osseous industry was relatively abundant, and included mainly small tools used in diverse crafts (awl, needles, spatulae, scrapers, chisels, etc.), heavy-duty tools (axes, adzes, percussion tools), hunting gear (projectile points and rare fishhooks) and jewellery (pendants, beads, bracelets, buckles). Bone was the predominant raw material, followed by red deer and more rarely roe deer (Capreolus capreolus) antlers, with occasional use of teeth and mollusc shells (Vitezović, 2011a). Most of the bone tool assemblages were collected during excavations carried out in the early and mid-20th century, and the faunal remains were not collected uniformly and carefully. Although some assemblages include several hundred tools and technical pieces, at most sites there are only a few well-preserved tools now stored in various museum collections.

Artefacts identified as retouchers/pressure-flaking tools were noted at seven sites: the eponymous site of Starčevo-Grad, Donja Branjevina and Ludaš-Budžak, located in Vojvodina, on the Pannonian Plain; and at Anište-Bresnica, Grivac, Divostin and Drenovac, situated in Pomoravlje, central Serbia (Vitezović, 2007, 2011a, 2013a, 2013b).

STARČEVO-GRAD Two tools with characteristic use traces were identified. The first is made from a small red deer antler tine. It has a blunt tip and its use traces consist of deep, dense notches and incisions. Its base features a deep groove, perhaps used for

![Figure 4](image-url)  a) Retouching tool from the site of Starčevo-Grad (Starčevo culture, Early Neolithic), made from roe deer antler; b) Detail of usewear.
attaching the tool (Figure 3). The second artefact was made from a roe deer antler segment, which consisted of the beam with a crown and one tine. The entire tine is covered by dense, deep, parallel incisions and grooves from use (Figure 4).

**DONJA BRANJEVINA** Three retouching tools were identified, all made from red deer antler tines. Two have their natural tine tips transformed into small, rounded surfaces (ca. 5 mm in diameter), blunt and worn from use (Figure 5). Fine traces of cutting related to manufacture can be observed at the proximal ends, and most of the naturally rough outer surfaces of the antlers were smoothed by scraping with a flint tool. Traces of use, visible on the distal portions of both tools, consist of partially overlapping, short and deep furrows, grooves and incisions, oriented perpendicular to the long axis of the tool.

The third tool was carefully made from the tip of a small antler tine (Figure 6). The base was carefully cut and the spongy tissue partially carved out. Nearly the entire outer surface was smoothed. The tool had perforations at the base, 4-5 mm in diameter – one entirely preserved, another broken and a third perforation was started, but remained un-
finished. The active end is partially damaged; nevertheless, its end has been modified into a semi-circular surface. Deep and dense lines, incisions and grooves, perpendicular to the long axis of the tool, are visible at the distal end. Perforations were probably made so that the artefact could be attached to a belt or otherwise carried on the body. The broken perforation likely resulted from such use.

**LUDAS-BUDZAK** One retouching tool was discovered, made from a red deer antler tine tip (Figure 7). The base was cut off and the entire surface is covered by dense use traces. In the distal portion of the tool, several zones exhibit overlapping grooves and diagonal incisions. The tip was modified into a circular surface and covered with dense lines and incisions.

**ANIŠTE-BRESNICA** One retouching tool was discovered, made from a red deer antler tine (Figure 8). The basal portion was cut off and the distal surface was smoothed by scraping with a fine chipped stone tool. The distal end was shaped into a small circular surface, and the entire distal portion of the tool is covered with deep, dense incisions and grooves.

**DIVOSTIN** A rich antler industry discovered at the site of Divostin included four retouching tools, all made from red deer antlers. Three tools were made from tines; the natural tips were shaped into a small
Figure 8  a, b) Retouching tool from the site of Anište-Bresnica (Starčevo culture, Early Neolithic); c, d) Detail of use; e) Detail of manufacture traces.
circular surface on two specimens, while the third object has a damaged tip that was previously modified by cutting. Traces of use are very intense on all specimens and consist of dense, deep incisions and grooves. The fourth artefact is a hammer made from the modified base of a shed red deer antler (Figure 9). The natural base was used as a hammer-like working surface, and the beam was thinned for use as a handle. The natural base of the antler was also modified (or possibly repaired) by removing small flakes prior to or during use as a hammering surface. The opposite end was not preserved. After the tool broke or became blunt, the handle was secondarily used for the manufacture of chipped stone artefacts; dense, deep, short incisions and furrows are visible on its surface.

GRIVAC Two retouching tools were identified, both made from small tine fragments of red deer antlers. The natural tips were modified into a circular surface on both tools (Figure 10). On the first tool, the tip was cut off by grooving and cutting; on the second, two flakes were removed from two sides by direct percussion. The outer surface of the first tool was also scraped with a flint tool. Apart from damage on the tip, the distal ends are entirely covered with incisions and grooves. One of the retouchers was discovered in an excavation unit associated with a pit dwelling and was possibly abandoned at the place where it was used.

DRENOVAC Two small antler tines were used as retouchers but only minimally modified. The first has traces of cutting at the base from gradual thinning with a flint tool; the natural antler tip was modified into a small circular surface by cutting. Its entire mesial and distal parts are covered with dense, somewhat irregular, short incisions and grooves, thus, forming a zone of damage caused by intensive use (Figure 11). The tip is blunt and damaged from use.

Figure 9 a, b) Hammer modified into retouching tool, from the site of Divostin (Starčevo culture, Early Neolithic); c) Detail of usewear.
The second retoucher is not completely preserved, but numerous incisions and grooves from use are visible on the distal part.

**Karanovo I culture**

The first farming communities in the Eastern Balkans, present-day Bulgaria, are labelled the Karanovo I culture (see Boyadzhiev, 2009, and references therein). The chipped stone industry is marked by macroblade technology, in particular by the presence of blades with high retouching, sometimes of considerable dimensions, and also by irregular blades, retouched flakes and perforators (see Gatsov and Nedelcheva, 2009, and references therein). As for the bone industry, the problem of sample bias is evident – faunal remains from most of the older excavations were not carefully collected nor examined for possible traces of manufacture and use. At present, only a few bone assemblages have been analysed in great detail, including Ovčarovo (Zidarov, 2014), Karanovo (Lang, 2005) and Yabalkovo (Guedeli, 2014), but no retouching tools were identified at any of these sites.

The recently excavated site of Nova Nadezhda, however, yielded possible tools related to retouching activities. The site is situated in eastern Thrace near the town of Khaskovo, Bulgaria, and was excavated as part of a rescue project in 2013-2014. Excavations revealed Early Neolithic settlement structures (houses, pits, ditches), several graves and archaeological remains from later periods (Bacvarov et al., 2014, 2015). In addition to numerous ceramic finds, many lithic and osseous artefacts were also uncovered.

The osseous industry from the Early Neolithic at Nova Nadezhda is relatively rich and includes some characteristic techno-types for this period, such as...
awls, needles, spoons, chisels, etc. Animal bone was the predominant raw material, followed by red and fallow deer (*Dama dama*) antlers, teeth and shells. In general, antler was poorly preserved, but did serve as the raw material for a number of small punching tools, scrapers and burnishers. One finely made but badly preserved specimen was discovered within the Early Neolithic ditch at Nova Nadezhda. This small hammer tool was completely smoothed and burnished and was made from a beam segment of either a red or fallow deer antler. It has traces of use that may be interpreted as retouching marks: deep, perpendicular incisions and punctiform pits creating clusters of heavy damage on the surface (Figure 12). Another interesting find is a fallow deer antler pedicle, discovered below a Chalcolithic structure, but most likely belonging to disturbed Early Neolithic layers. This implement includes no traces of manufacture, but preserves dense traces of use in the form of short, deep incisions and grooves on its surface (Figure 13). It was most likely used as an anvil or support.

**Retouching tools in the Late Neolithic**

*Vinča culture*

The *Vinča* culture represents the Late Neolithic/Early Chalcolithic culture in the central Balkans and south Pannonian region (present-day Serbia, Oltenia and Transylvania in Romania, eastern parts of Croatia and Bosnia and Herzegovina), covering the time span between 5400 and 4500/4450 cal BC (Borić, 2009; Tasić et al., 2015).

The *Vinča* culture is characterized by developed craft production (Tringham and Krstić, 1990), with rich lithic and osseous industries. Chipped stone industries are generally abundant and included both local raw materials and imported obsidian. Retouched tools, including flakes, blades, scrapers, etc., were present in varying abundances at different sites and over time (Kaczanowska and Kozlowski, 1990; Antonović and Šarić, 2011). Osseous assemblages mainly included tools for diverse crafts: awls, needles, spoons, chisels, etc. Animal bone was the predominant raw material, followed by red and fallow deer (*Dama dama*) antlers, teeth and shells. In general, antler was poorly preserved, but did serve as the raw material for a number of small punching tools, scrapers and burnishers. One finely made but badly preserved specimen was discovered within the Early Neolithic ditch at Nova Nadezhda. This small hammer tool was completely smoothed and burnished and was made from a beam segment of either a red or fallow deer antler. It has traces of use that may be interpreted as retouching marks: deep, perpendicular incisions and punctiform pits creating clusters of heavy damage on the surface (Figure 12). Another interesting find is a fallow deer antler pedicle, discovered below a Chalcolithic structure, but most likely belonging to disturbed Early Neolithic layers. This implement includes no traces of manufacture, but preserves dense traces of use in the form of short, deep incisions and grooves on its surface (Figure 13). It was most likely used as an anvil or support.
needles, massive pointed tools, spatulae, scrapers, chisels, axes, hammers and other percussion tools. Hunting and fishing gear (harpoons, fishhooks) and jewellery (bracelets, pendants, appliqués) were made mainly from domestic animal bones, red and roe deer antlers, boar tusks and mollusc shells, including imported *Spondylus* (Bačkalov, 1979; Lyneis; 1988, Russell, 1990; Vitezović, 2007, 2013a).

Retouching tools were rare, identified at only two sites thus far: Selevac and Drenovac, both in the Pomoravlje region of Serbia. At Selevac, at least four tools have been identified as pressure flakers (Russell, 1990), three made from antler and one from a rib segment. All have been shaped into a broad, blunt point, and the area beneath the tips show clusters of characteristic scars. Several other artefacts have unclear or poorly preserved micro-wear, but are likely to have been used for pressure flaking, including three lozenge-shaped pieces of antler.

Two retouching tools were discovered within the Starčevo culture layers at Drenovac. Another retouching tool made from a large red deer antler tine

![Figure 13](image13a.png) a) Antler pedicle with traces of use, probably as an anvil for retouching, from the site of Nova Nadezhda (Early Neolithic); b) Detail usewear.
likely belongs to the Vinča culture layers (Vitezović, 2007). Its tip is damaged, but several deep, overlapping horizontal grooves from use are visible on the distal end.

*Neolithic in Europe*

Retouching tools have been reported from a few Neolithic sites in central and western Europe.

In Hungary, the Late Neolithic site of Aszód Papi yielded a very rich osseous industry, including 90 pieces used as intermediate punches or pressure flakers. All were made from red deer antlers, except for three made from roe deer antlers (Tóth, 2013). From the Pre-Cucuteni site of Târgu Frumos in Romania, three pieces made from red deer antler segments were probably used for retouching stone (Vornicu, 2013).

A total of 29 antler retouching tools were also reported from Chalain 4 in France (Maigrot, 2003). All were all made from elongated segments of red deer antler tines modified by abrasion, except for one roe deer crown and one basal segment. They were used both for retouching by compression and by percussion. In fact, careful microscopic examination at high magnifications allowed Maigrot (2003) to distinguish 15 percussion and 14 retouching tools. Some of these tools were re-utilized, originally functioning as cutting/chopping tools or “sleeves” for hafting stone axes.

Finally, the most interesting and probably the most recent of these finds comes from the equipment carried by the mummy, known as Ötzi, discovered in the Ötzal Alps on the border between Austria and Italy. Amongst other possessions, he carried one tool made from a section of a stripped lime tree branch, which was cut off at one end and sharpened at the other. An antler rod, 6.1 cm long, was hammered into the core of the branch, so the total tool length was 11.9 cm, although the antler spike stuck out no more than 4 mm. The distal end of the antler had also been hardened by firing. The tool was easily sharpened like a pencil when the antler tip became blunt from use (Spindler, 1995; Fleckinger and Steiner, 2000). This tool, with its bark haft, is a unique find in prehistoric Europe, and provides insight into how these tools were used during the Neolithic and earlier times.

Chalcolithic bone industries from European contexts are insufficiently studied; therefore, the presence or absence of retouching tools cannot be adequately assessed. In southeast Europe, retouching tools are absent from carefully collected and thoroughly analysed assemblages, such as from the site of Bubanj in Serbia (personal observation) and from Chalcolithic layers at Karanovo in Bulgaria (Lang, 2005). However, as mentioned earlier, sample bias may be a contributing factor to this apparent absence.

*Discussion*

The evidence for osseous retouching tools in the Mesolithic period is relatively sparse. To date, such tools have been reported from northeastern Europe and from the Iron Gates region. However, studies of the material from recent excavations (Radović, et al., 2016), as well as re-examinations from older excavations (David and Sørensen, 2016), show that the distribution and overall quantity of osseous tools used in stone working are much higher than the current results suggest. Although the relatively small number of known retouching tools does not allow for generalizations, some trends can be noted. The predominant raw material is antler, followed by teeth and the occasional use of the other skeletal elements. The retouchers are also rarely unworked, *ad hoc* artefacts, but rather intentionally shaped tools. Furthermore, they were used for longer periods and sometimes even re-worked and repaired.

The preference for antlers continues into the Neolithic period. In the Starčevo culture, except for one roe deer antler tool from the Starčevo site, all artefacts were made from red deer antler segments. The possible use of fallow deer antlers is also noted in the Thrace region. Tine tips were preferred, although other antler segments may be encountered. The natural tips of the tines are usually shaped into smaller circular or elliptical surfaces, and sometimes
entire tools were smoothed by scraping and burnishing. In most cases, the tools resemble small punches made from truncated antler tines. It is possible that some of the punches were also used for retouching, but the characteristic use traces were not preserved or the retouchers were used for too short a time for the traces to be visible.

The retouchers in the Vinča culture are mainly modified antler tines as well, similar to small punching tools. Additional retouching tools may be unidentified, either because the assemblages were not examined carefully or the use traces were not well preserved.

If we arrange retouchers from Starčevo sites along an imaginary manufacturing continuum (sensu Choyke, 1997, 2001; Choyke and Schibler, 2007), they cover a wide range, from minimally modified tools to carefully made pieces involving considerable investments in time and labour. Strictly ad hoc objects are absent, but broken antler tools were sometimes secondarily used as retouchers (e.g., the broken hammer from Divostin; see Figure 9). The manufacture of most of the tools was planned – they were made in a uniform way from strictly chosen raw material. Some of the specimens are very well crafted, particularly the piece from Donja Branjevina (see Figure 6), with its carefully cut basal part and basal perforations. Traces of repair can also be observed on this particular tool. After one of the perforations broke, another one was started but not finished; perhaps the remaining perforation was sufficient or the distal end broke off and the tool became unusable. This tool and another example from Starčevo were probably portable (see Figure 3) – they could have been worn attached to the belt, at hand and ready for use. Such carefully made examples have not been discovered in Vinča culture assemblages thus far. However, the Vinča retouching tools discovered were planned and worked artefacts, not simple ad hoc tools.

Examples from the Neolithic sites in Switzerland display similar patterns: antler was the preferred raw material, strictly ad hoc tools were not noted and there are a few carefully shaped examples that were likely worn on a belt.

Extended use lives, as well as considerable time and labour investments, suggest these tools held some importance in craft production. The possibility that some of these tools were worn visibly argues in favour of the idea that the skill these tools implied were valued (Choyke and Schibler, 2007). However, the available data does not allow any further generalizations regarding their exact position within the organisation of production. Were they used frequently or only occasionally? Were retouchers made from osseous raw materials rare or common? What was their relation to retouching tools made from stone materials? These questions remain unanswered.

Most Neolithic retouching tools were used for a long time, sometimes even repaired. Preserved use traces suggest that they were used for both percussion and pressure flaking. Detailed microscopic examination of the retouching tools from Chalain 4 demonstrated both functions were equally represented (Maigrot, 2003). Examined under low magnification, use traces on the pieces from the Starčevo culture can be roughly divided into two groups: 1) incisions and grooves, perpendicular or diagonal to the long axis of the tool, located around the small circular working end; and 2) use areas consisting of dense concentrations of incisions, grooves and furrows, located across the surfaces, especially in the distal portion. These different types of damage suggest two modes of use: for percussion and pressure flaking. Some of the tools were used in both ways, but some have preserved just one type of use trace (Vitezović, 2011a).

**Conclusion**

Flint-knapping represented a valued skill, not just for early humans, but also throughout the entire prehistoric period. Knowledge of flint-knapping itself was valued, and the resulting artefacts, with their investments in labour and time, could have been objects of prestige (Sinclair, 1995, 1998; Hayden, 1998). Retouchers represent one of the most widespread tool types made from osseous raw materials,
covering a wide chronological and geographical distribution. They are also made from a wide range of raw materials, different tools include various levels of modification and their final shapes are variable.

The study of retouching tools, their first appearances, distribution, raw material choices, etc., is important for studying human technological behaviour. In the Holocene, when important changes occurred in most segments of life (e.g., subsistence practices, lifeways, worldviews), retouching tools also underwent certain changes that reflect transformations in overall technological practices. Ad hoc use of osseous remains declined, and more careful selection of raw materials is notable. In the eastern European Mesolithic, retouching tools were made from carnivore and beaver teeth, as well as antlers, while antler was the preferred raw material in most other Mesolithic and Neolithic communities. Unlike during the Palaeolithic period when all osseous raw materials were used, often without any selection (Leonardi, 1979; Leroy-Prost, 2002; Valensi, 2002; Schwab, 2003; Mozota, 2007; see also Patou-Mathis, 2002, and references therein), the predominance of antler is apparent in the Mesolithic and Neolithic. Antler is generally more resilient to shock and more convenient for use as a percussion tool (Billamboz, 1977; see also Christensen, 2004, and references therein); therefore, such a preferred raw material choice may be related to the less expedient character of these tools and their longer duration of use.

Over time, retouchers became planned tools, sometimes very skilfully made, with considerable time and labour invested in their manufacture. They were often used for a long time and repaired. Some retouching tools were even made publicly visible (possibly hanging from the belt), perhaps giving to their owner a certain status.

Future detailed examination of already recovered faunal remains or new excavations will certainly add to the quantity and morpho-typological diversity of retouching tools from the Holocene period. Judging from the currently available data, retouching tools gradually disappear from the Chalcolithic period in most parts of Europe, when the overall technology underwent dramatic changes largely related to the introduction of metallurgy.

Acknowledgments

This paper is the result of work on the projects “Archaeology of Serbia: cultural identity, integrational factors, technological processes and the role of the central Balkans in the development of the European prehistory”, no. OI 177020, and “Bioarchaeology of ancient Europe: humans, animals and plants in the prehistory of Serbia”, no. III 47001, funded by the Ministry for Education, Science and Technological Development of the Republic of Serbia. I would like to thank my colleagues who entrusted me with the material analysed here: Krum Băcvarov, National Archaeological Institute with Museum – BAN, Sofia; Dario Vujević, Department of Archaeology, University of Zadar; Andrej Starović, National Museum in Belgrade; Maja Živković, Institute for the Cultural Heritage Preservation, Pančevo; Jelena and Vojislav Đorđević, National Museum in Pančevo; Agnes Sekeres, City Museum of Subotica; Nebojša Vidović, Museum Department in Odžaci; Branka Zorbić, National Museum in Kragujevac; Katarina Dmitrović, National Museum in Kraljevo; Vesna Živanić, Regional Museum in Paraćin. Also, I would like to thank the colleagues who helped me with references: Dale Serjeantson, Herbert Böhm, Hans Christian Küchelmann, Zsuzsanna Tóth, Éva David, Jörg Schibler and Mikhail Zhilin. Last but not least, I am grateful to the conference organizers and to the anonymous reviewers.
